## Section 2.4 International Units of Measure

SI (Système International) is a system of measurement developed in France around the time of the revolution in the 1790's. It is used worldwide because calculations and conversions are easier than other systems. There are three countries in the world still officially using non-metric systems of measure: Liberia, Myanmar, and the US. The seven base units and their respective quantities are in the table below

| Base quantity | Base unit name | Base unit symbol |
| :--- | :--- | :--- |
| Length | metre | m |
| Mass | kilogram | kg |
| Time | second | s |
| Electric current | ampere | A |
| Temperature | kelvin | K |
| Amount of <br> substance | mole | mol |
| Intensity of light | candela | cd |

In the SI system, each type of unit, for example the metre or the gram, is used as a base. Then to change the unit of measure, you just need to use the system of prefixes given below.

| Prefix | tera | giga | mega | kilo | hecto | deca | deci | centi | milli | micro | nano |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Symbol | T | G | M | k | h | da | d | c | m | $\mu$ | n |
| Conversion <br> factor | $10^{12}$ | $10^{9}$ | $10^{6}$ | $10^{3}$ | $10^{2}$ | $10^{1}$ | $10^{-1}$ | $10^{-2}$ | $10^{-3}$ | $10^{-6}$ | $10^{-9}$ |

Below are non-SI units defined in terms of SI units.

| Quantity | Name of unit | Symbol | Equivalents in SI units |
| :---: | :---: | :---: | :---: |
| time | minute | $\min$ | $1 \mathrm{~min}=60 \mathrm{~s}$ |
|  | hour | h | $1 \mathrm{~h}=60 \mathrm{~min}=3600 \mathrm{~s}$ |
|  | day | d | $1 \mathrm{~d}=24 \mathrm{~h}=86400 \mathrm{~s}$ |
| area | hectare | ha | $1 \mathrm{ha}=1 \mathrm{hm}^{2}=10^{4} \mathrm{~m}^{2}$ |
| volume | litre | $\mathrm{L}, \ell$ | $1 \ell=1 \mathrm{dm}^{3}$ |
| mass | tonne | t | $1 \mathrm{t}=10^{3} \mathrm{~kg}$ |

There are three temperature scales. Kelvin $(\mathrm{K})$ is the only SI base unit and is mainly used by scientists. Celsius (C) is an SI derived unit used in most countries. A few other countries, including the United States use Fahrenheit (F). At the right is a table comparing Freezing and

| Scale | Freezing point <br> of water | Boiling point <br> of water |
| :---: | :---: | :---: |
| Fahrenheit $\left({ }^{\circ} \mathrm{F}\right)$ | 32 | 212 |
| Celsius $\left({ }^{\circ} \mathrm{C}\right)$ | 0 | 100 |
| Kelvin $(\mathrm{K})$ | 273.15 | 373.15 | Boiling Points in each scale.

To convert from one SI unit of measure to another, either multiply or divide by the appropriate power of 10 .

Example: Convert 34 km to cm
Using the diagram as a guide, I am going to the right. So I would multiply by $10^{5}$.

$$
34 \mathrm{~km} \times 10^{5}=3,400,000 \mathrm{~cm}
$$

Or if it is easier, convert km to m and then m to cm ... $1 \mathrm{~km}=1000 \mathrm{~m}$ so $34 \mathrm{~km}=34,000 \mathrm{~m}$ 1 meter $=100 \mathrm{~cm}$ so $\Rightarrow 34,000 \times 100=3,400,000 \mathrm{~cm}$

Example: The volume of a vase is 1570 ml . Find the volume of the vase in litres.
There are a 1000 milliliters in a liter. Since I am going to a "larger" unit I will divide.

$$
\frac{1570}{1000}=1.57 \text { litres }
$$

Remember that when converting a unit of area or volume, each unit needs to be converted. For instance, if converting a volume in $m^{3}$ to $\mathrm{cm}^{3}$ you have to convert $m \times m \times m$ to $\mathrm{cm} \times \mathrm{cm} \times \mathrm{cm}$.

Example: A field is 91.4 m long and 68.5 m wide.
a. Calculate the area of the field in $\mathrm{m}^{2}$
$(91.4)(68.5)=6260.9 \mathrm{~m}^{2}$
b. Calculate the area of the field in $\mathrm{cm}^{2}$

So to convert $m$ to cm I would multiply by 100 . Since I need $\mathrm{cm}^{2}$ I would multiply by $100^{2}$

$$
6260.9 \mathrm{~m}^{2} \times 100^{2}=62,609,000 \mathrm{~cm}^{2}
$$

Example: The speed of sound in air is given as $300 \mathrm{~ms}-1$ (meters per second). How many metres does sound travel in air in one hour?

There are 60 seconds in a minute and 60 minutes in an hour.
That means $(60)(60)=3600$ seconds in an hour.
So meters per hour would be $(300)(3600)=1,080,000$ meters

Example: The SI unit for force is the newton. If $\mathrm{F}=m a$ where F is the force on an object, $m$ is the object's mass in kg , and $a$ is the acceleration of the object in $\mathrm{m} \mathrm{s}^{-2}$ (meters per second ${ }^{2}$ ), find the units of a newton in terms of $\mathrm{kg}, \mathrm{m}$, and s .

Just substitute the units into the formula

$$
\mathrm{F}=m a=(\mathrm{kg})\left(\mathrm{m} \mathrm{~s}^{-2}\right)=\mathrm{kg} \mathrm{~m} \mathrm{~s}^{-2}
$$

Example: The density $\rho$ of an object is equal to the mass of the object divided by the volume of object. If the dimensions of a 1 kg cube of metal are 10 cm on each side, find the density of the cube in $\mathrm{kg} \mathrm{m}^{-3}$

First convert 10 cm to meters.

$$
\frac{10}{100}=0.1 \text { meters }
$$

So if it is a cube, the volume of the cube would be $(0.1)^{3}=0.001 \mathrm{~m}^{3}$
To find the density...

$$
\rho=\frac{\text { mass }}{\text { volume }}=\frac{1 \mathrm{~kg}}{0.001 \mathrm{~m}^{3}}=1000 \mathrm{~kg} \mathrm{~m}^{-3}
$$
